Abstract: Coated Co$_9$S$_8$/carbon nanotube (Co$_9$S$_8$/2CNTs) microspheres were constructed and successfully applied to aqueous ammonium-ion batteries. The introduction of carbon nanotubes in the Co$_9$S$_8$ microspheres increased the electronic conductivity, shortened the diffusion distance for NH$_4^+$ ions and improved the buffering ability against volume changes in the cycling processes. As a result, Co$_9$S$_8$/2CNTs microspheres had a reversible capacity of 112 mA·h/g at 0.1 A/g. In addition, the ammonium ion energy storage mechanism accompanied by the formation of reversible phase transition product CoSO$_4$·6H$_2$O and establishment/breaking of intermolecular hydrogen bonds in Co$_9$S$_8$/2CNTs was investigated.

Key words: cobalt sulfide; carbon nanotubes; ammonium-ion batteries; composite microspheres; hydrogen bond

1 Introduction

Aqueous rechargeable batteries have great potential in large-scale energy storage applications due to their high safety, fast ionic conductivity, low cost and environmental friendliness. Since DAHN et al designed the first aqueous lithium-ion battery in 1994, numerous metal ions, such as K$^+$ [1], Na$^+$ [2], Zn^{2+} [3,4], Mg^{2+} [5], Ca^{2+} [6] and Al^{3+} [7], have been widely investigated as charge carriers. In recent years, aqueous nonmetal ion batteries [8] such as NH$_4^+$ [9], H$^+$ [10] and H$_3$O$^+$ [11] have received increasing attention. Compared with metallic charge carriers, nonmetallic charge carriers are irreplaceable, especially when their almost infinite resources are given. Among nonmetal cations, NH$_4^+$ ions as charge carriers have revealed more prominent attractions in less corrosive and lower hydrogen evolution, ultrafast ion diffusion kinetics in aqueous electrolytes and sustainable developments for safety, abundant resources and low cost in the energy storage fields [12,13]. It is worth noting that Li$^+$, Na$^+$, and K$^+$ are monoatomic spherical ions with a nonpreferential orientation, while NH$_4^+$ ions are tetrahedral polyatomic ions [14]. Different intercalation chemistry from monoatomic spherical ions and tetrahedral polyatomic ions could bring about unique topological chemistry or ionic diffusion mechanisms.

Since the pioneering attempt of WESSELLS et al [15] on the Prussian blue [16] analog KM[Fe(CN)$_6$] (M=Cu and Ni), various electrode materials, such as conducting the polymers (polyaniline [17], PTMA [18]) and metal oxides (V$_2$O$_5$ [19], MnO$_x$ [20], titanic acid [21], NH$_4$V$_4$O$_{10}$ [22], MoO$_3$ [23], WO$_3$ [24]), have been used for NH$_4^+$ storage. For example, DONG et al [19]

reported that V_2O_5 could act as an NH_4^+ host through H-bonds. The hydrogen bonding chemistry was investigated by comparing the electrochemical behavior of NH_4^+ and K^+ in the V_2O_5 host. Recently, SONG et al [20] reported the electrochemical deposition of manganese oxide (MnO_x) for NH_4^+ storage. Systematic experimental evidence and computational studies have shown the continuous building/breaking of hydrogen bonds between NH_4^+ and MnO_x layers.

The metal sulfides exhibited extraordinary potential in electrochemical energy storage fields but were hardly involved in aqueous ammonium-ion energy storage. Co_9S_8 has gained considerable attention in electrochemistry fields due to its inherent mixed valences and metallic behavior. However, Co_9S_8 exhibited poor cycling stability and rate performance owing to the volume change and dissolution of active materials during the charge and discharge processes. The combinations of Co_9S_8 and carbon-based materials were considered a promising solution [25]. The introduction of carbonaceous materials could effectively increase the electrical conductivity, alleviate the volume expansion and inhibit the dissolution of active materials during the charge and discharge processes [26,27]. Carbon nanotubes (CNTs) are promising nanocarbon materials with excellent electrical conductivity, large specific surface area, chemical stability and excellent mechanical flexibility that can modify Co_9S_8 particles [28,29]. In particular, Co_9S_8 coupled with carbon nanotubes as a cathode material for ammonium ion batteries has rarely been reported.

Herein, coated Co_9S_8/carbon nanotube (Co_9S_8/2CNT) microspheres were constructed and successfully applied in aqueous ammonium-ion batteries. The Co_9S_8/2CNTs microspheres exhibited a high capacity, excellent cycling stability and good rate performance. Some Co_9S_8 in Co_9S_8/2CNTs microspheres underwent reversible phase transformation to form $CoSO_4·6H_2O$ during the charge/discharge processes, while the reaction kinetics of the electrodes, including the evolution of the first-cycle transport kinetics, was further investigated to demonstrate the pseudocapacitive properties of NH_4^+ embedding/de-embedding behavior in Co_9S_8/2CNTs microspheres, and the diffusion process was always accompanied by uninterrupted intermolecular hydrogen bond building/breaking. This investigation provided a promising strategy for aqueous ammonium-ion storage.

2 Experimental

2.1 Synthesis of Co_9S_8

Co_9S_8 was prepared by solvothermal method. 4.3572 g cobalt acetate tetrahydrate and 1.3332 g thiourea were dissolved in 100 mL ethylene glycol and stirred under magnetic stirrers for 30 min. The uniform solution was transferred to a 100 mL Teflon lined stainless steel reactor for hydrothermal reaction at 200 °C for 48 h. The product was collected by centrifugation at a speed of 6000 r/min for 20 min, washed with ethanol and deionized water for several times, and dried in a vacuum drying oven at 60 °C for 3 h.

2.2 Synthesis of Co_9S_8/2CNTs

2 wt.% CNTs coated Co_9S_8 (Co_9S_8/2CNTs) was prepared by solvothermal method. 0.5 g Co_9S_8 and 0.1 g CNTs were dispersed in 100 mL ethylene glycol (the control group was 0.5 g Co_9S_8 dispersed in 100 mL ethylene glycol), stirred under magnetic stirrers for 30 min, and the homogeneous solution was transferred to a 100 mL PTFE-lined stainless steel reactor for hydrothermal reaction. The reaction temperature was 200 °C, and the reaction time was 24 h. The obtained product was centrifuged at 6000 r/min for 20 min, washed with ethanol and deionized water for several times, and dried in a vacuum drying oven at 60 °C for 3 h.

3 Results and discussion

3.1 Phase structure and chemical component analysis

Figure 1(a) shows the XRD patterns of the Co_9S_8 and Co_9S_8/2CNTs microspheres. The diffraction peaks of the two microspheres were attributed to cubic Co_9S_8 phase (PDF# 65-1765). The CNT diffraction peaks were invisibly observed in the Co_9S_8/2CNT microspheres due to the low CNT content. Nevertheless, the presence of CNTs could be confirmed by Raman spectra (Fig. 1(b)). The two obvious peaks positioned at 1333 and 1589 cm^{-1} could be assigned to the D-band induced by disordered carbon and the G-band related to graphitized carbon, respectively. The ratio of the
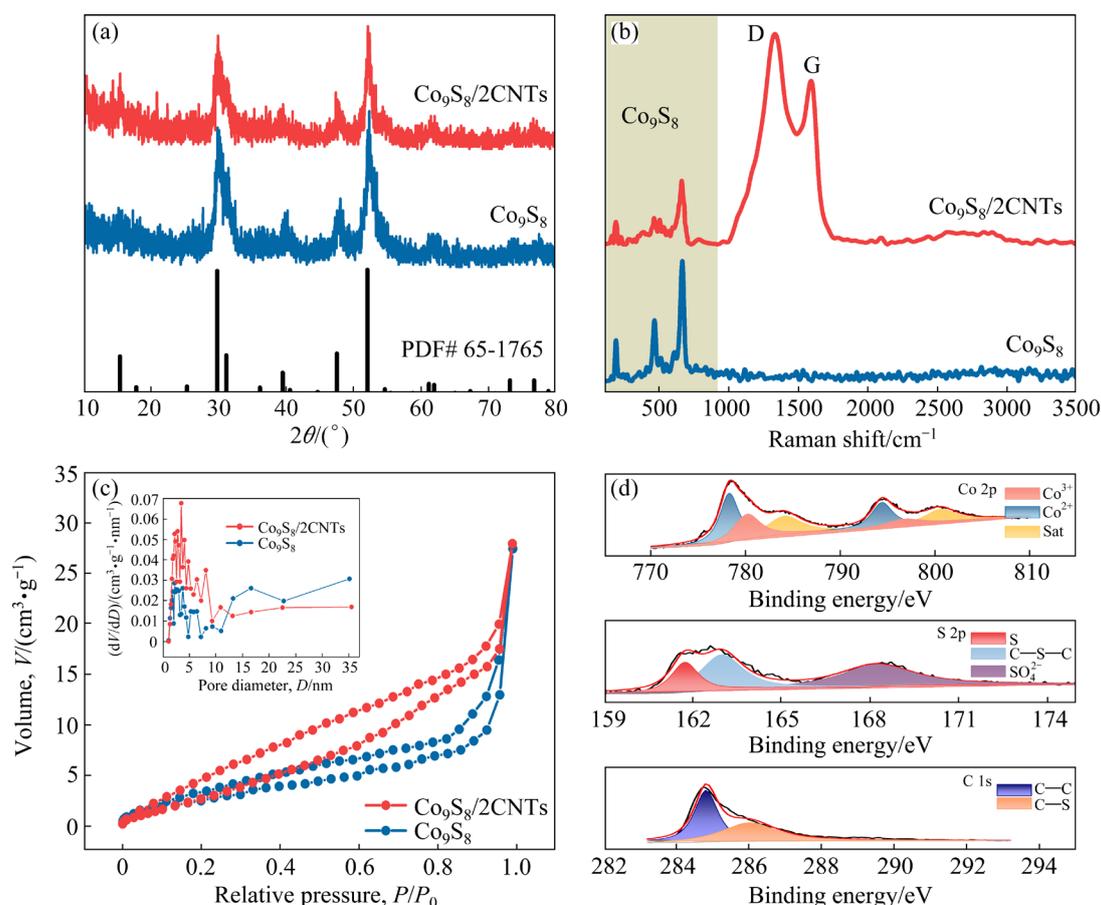

Fig. 1 XRD patterns (a), Raman spectra (b) and nitrogen adsorption−desorption isotherms (c) of Co_9S_8 and Co_9S_8/2CNTs, and XPS spectra of Co 2p, S 2p and C 1s in Co_9S_8/2CNTs sample (d)

D-band and G-band intensities (I_D/I_G) was 1.16:1, indicating the formation of abundant defect structures in the CNTs; this demonstrated that the incorporation of CNTs could provide additional defect sites for NH_4^+ storage and further enhance the electrochemical properties of Co_9S_8/2CNTs microspheres. Some weak bands below 750 cm^{-1} were perfectly indexed to Co_9S_8 crystals.

The specific surface area and pore size distribution of the microspheres were determined by the N_2 adsorption−desorption method. The two microspheres both exhibited typical IV isotherms and H3-type hysteresis loops, indicating the presence of microporous and mesoporous structures in the two microspheres (Fig. 1(c)). The specific surface area of the Co_9S_8/2CNTs microspheres was calculated to be 40.72 m^2/g, which was significantly higher than that of Co_9S_8 (12.20 m^2/g). The pore size distribution curves (inset in Fig. 1(c)) also showed that Co_9S_8/2CNTs microspheres had more abundant micropores and a relatively narrow pore size distribution than Co_9S_8 microspheres, which

could accelerate the ion transfer and reduce the volume change during the cycling processes to improve the electrochemical properties of the materials.

The elemental composition and surface chemical state of Co_9S_8/2CNTs microspheres were further determined by XPS methods (Fig. S1 in Supporting Information (SI)). The binding energies of Co 2p$_{3/2}$ and Co 2p$_{1/2}$ ranged from 778 to 786 eV and from 793 to 803 eV, respectively (Fig. 1(d)). The peaks centered at 784.4 and 800.4 eV were satellite peaks for Co 2p$_{2/3}$ and Co 2p$_{1/2}$, respectively. The binding energies at 780.2 and 796.9 eV could be attributed to Co^{2+}, while those at 778.3 and 794.1 eV belonged to Co^{3+} [30,31]. Furthermore, the S 2p XPS spectrum was fitted to three peaks, which could be attributed to S in Co_9S_8 (162 eV), C—S—C (163.5 eV) and SO_4^{2-} (167.6 eV). The presence of SO_4^{2-} should be related to the partial surface oxidation of the sample [32]. The high-resolution XPS spectrum of C 1s revealed two peaks at approximately 284.8 eV for C—C

bonds and 285.5 eV for C—S bonds [33]. The C—S peaks were ascribed to the single bond between Co_9S_8 and carbon, demonstrating that carbon nanotubes were tightly attached to Co_9S_8. The above results further elucidated the chemical composition of Co_9S_8/2CNTs microspheres, which was consistent with the XRD patterns and Raman spectrum analysis.

Figure 2 shows a schematic diagram of the Co_9S_8 crystal structure. The structure consisted of two polyhedra for CoS_6 octahedra and CoS_4 tetrahedra, where each CoS_6 octahedron shared its six angles with 24 CoS_4 tetrahedra. Nine cobalt atoms in each formula occupied two Witkoff positions, CoI (4b) and CoII (32f), and eight sulfur atoms occupied two different Witkoff positions, SI (8c) and SII (24e). CoI coordination was formed from six SI atoms to form the CoS_6 octahedron, and CoII coordination was composed of one SII and three SI atoms to form the CoS_4 twisted tetrahedron [34].

3.2 Morphology and microstructure

Figure 3 shows SEM and TEM images, and EDS mappings of Co_9S_8 and Co_9S_8/2CNTs micro-

Fig. 2 Crystal structure and its partial enlargement

spheres. The inhomogeneous clustered microspheres could be distinguished from Figs. 3(a, b). The typical high-resolution transmission electron microscopy (HRTEM) images exhibited the single-crystal of Co_9S_8 microspheres with d spacings of 2.64 Å and 2.54 Å (Figs. 3(c, d)), corresponding to the (400) and (004) crystal planes, respectively. The corresponding Fourier transforms (FFTs) of the

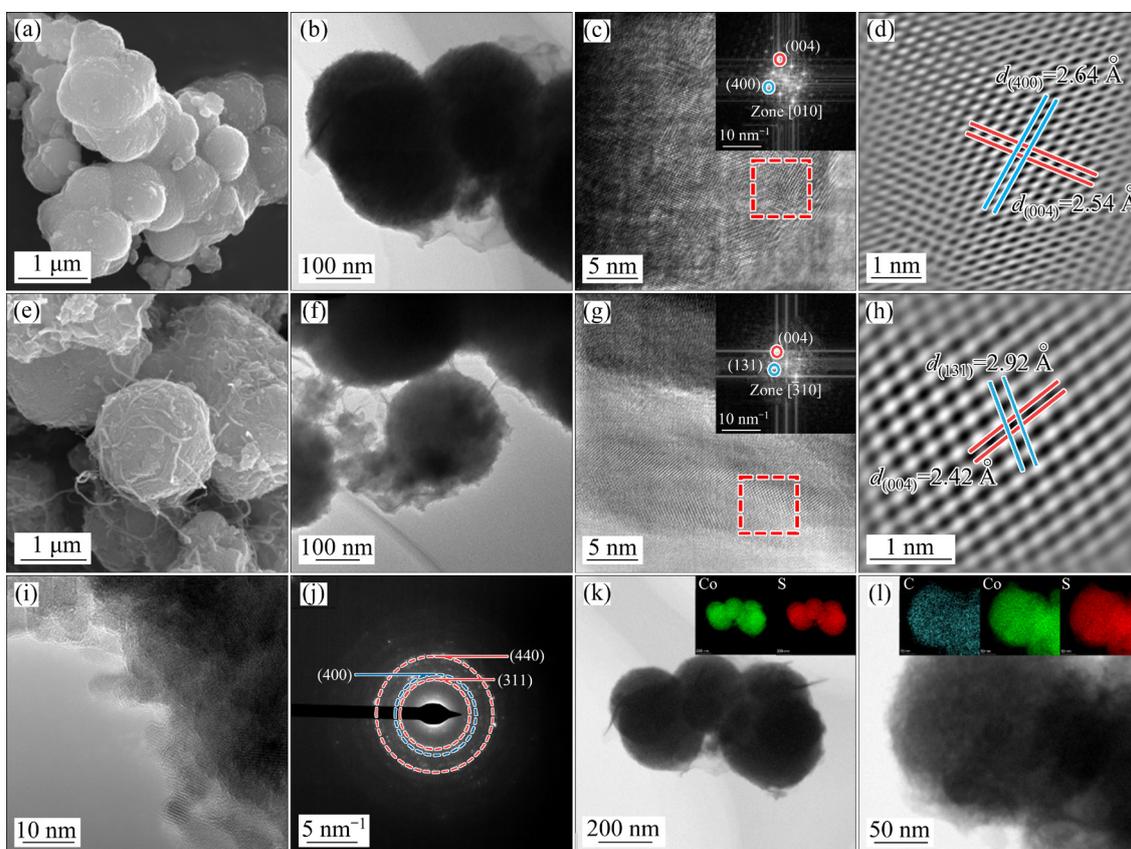

Fig. 3 SEM (a) and TEM (b−d) images of Co_9S_8, SEM (e) and TEM (f−i) images of Co_9S_8/2CNTs, selected area electron diffraction (SAED) diagram of Co_9S_8/2CNTs (j), and EDS mappings of Co_9S_8 (k) and Co_9S_8/2CNTs (l)

selected regions could be identified as cubic symmetric structures (inserted in Fig. 3(c)), which was in good agreement with the Co_9S_8 spatial structure (Fig. 2). For the Co_9S_8/2CNTs microspheres, the uniform and disperse microspheres were related to the CNTs (Figs. 3(e, f)). The HRTEM observations for the Co_9S_8/2CNTs microspheres (Figs. 3(g, h)) revealed crystal spacings of 2.92 nm and 2.42 nm, corresponding to (131) and (004) crystal planes, which were evidenced by the inserted FFTs (Fig. 3(g)). The three typical diffraction rings (Fig. 3(j)) could be attributed to (311), (400) and (440) planes of the Co_9S_8 phase (PDF# 65-1765). The EDS mapping images (Figs. 3(k, l)) for the Co_9S_8 and Co_9S_8/2CNTs microspheres confirmed the perfect overlap of Co and S but a slight extension of C due to the CNT combinations. The introduction of CNTs could inhibit the aggregation of active particles, alleviate electrode expansion to improve the structural stability during the cycling processes and enhance the electrical conductivity to increase the rate capability.

3.3 Electrochemical performance

The electrochemical performances of the Co_9S_8 and Co_9S_8/2CNTs microspheres were evaluated. Figures 4(a, b) display the typical charge−discharge curves of the Co_9S_8 and Co_9S_8/2CNTs microsphere electrodes at a current density of 0.1 A/g. The initial charge/discharge specific capacities were 186.4 and 113.2 mA·h/g for the Co_9S_8/2CNTs microspheres and 195.8 and 112.5 mA·h/g for the Co_9S_8 microspheres. The poor coulombic efficiency indicated irreversible reactions in the initial ammonization and deammonization processes. Although the Co_9S_8 and Co_9S_8/2CNTs microspheres exhibited almost identical discharge capacities in the initial cycle, they emerged with completely different capacity trends in the subsequent cycles. The Co_9S_8 microspheres suffered a continuous capacity decay with 95.3% capacity retention (107.2 mA·h/g) after 50 cycles. However, the discharge capacity for the Co_9S_8/2CNTs micro-spheres exhibited an evident increase at the second cycle followed by a sustained rise to 142.5 mA·h/g.

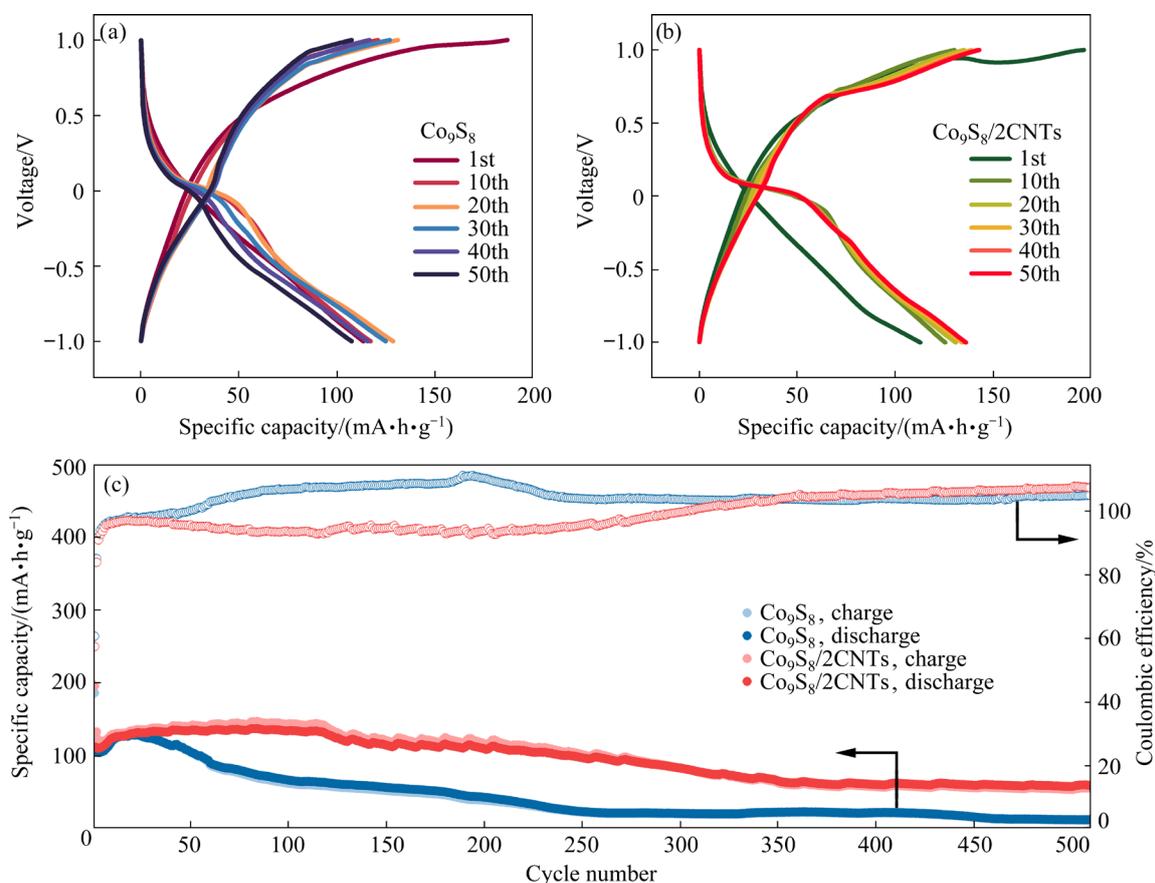

Fig. 4 Electrochemical performance of Co_9S_8/2CNTs cathode in voltage window from −1 to 1 V: (a) Charge–discharge curves of Co_9S_8 at 0.1 A/g; (b) Charge–discharge curves of Co_9S_8/2CNTs at 0.1 A/g; (c) Cyclic performance of Co_9S_8 and Co_9S_8/2CNTs at 0.1 A/g for 500 cycles

Compared with the Co_9S_8 microspheres, the Co_9S_8/2CNTs microspheres had significantly improved cycling stability after 500 cycles at a current density of 0.1 A/g (Fig. 4(c)). The Co_9S_8/2CNTs microspheres revealed a discharge capacity of 60 mA·h/g at the 500th cycle, which was markedly higher than that of the Co_9S_8 microspheres (13 mA·h/g). This result confirmed that the addition of CNTs could reduce the dissolution of Co_9S_8 polysulfides in the aqueous electrolyte, effectively buffering the large volume change of the Co_9S_8 microspheres during the discharge/charge processes [33,35]. The rate capabilities of Co_9S_8/2CNTs microspheres were investigated by changing the current density from 0.1 to 10.0 A/g (Fig. 5(a)). The Co_9S_8/2CNTs microspheres obtained an evidently higher capacity than the Co_9S_8 microspheres at any current density. The capacities for the Co_9S_8/2CNTs microspheres varied from 112 to 66 mA·h/g as the current

densities increased from 0.1 to 10.0 A/g. When the current density was restored to 0.1 A/g, the capacity of Co_9S_8/2CNTs microspheres could recover back to 110 mA·h/g, indicating a good rate performance.

Figure 5(b) depicts the CV curves of the Co_9S_8/2CNTs microspheres in the voltage window between −0.5 and 1.2 V at different scanning rates from 0.4 to 1.0 mV/s. The two pairs of redox peaks could be obviously observed on the Co_9S_8/2CNTs microspheres, which was similar to the results of Co_9S_8 in lithium-ion batteries [25], indicating that the Co_9S_8/2CNTs microspheres manifested NH_4^+ energy storage. In the cathodic scanning, there were two reduction peaks at −0.4 and 0 V, which were related to NH_4^+ insertion in the Co_9S_8 host. In the anodic scanning, the oxidation peaks at 0.3 and 0.85 V approximately were attributed to NH_4^+ extraction in the Co_9S_8 host [36]. The totally stored charges were derived from the capacitive processes, including pseudocapacitors, double layer

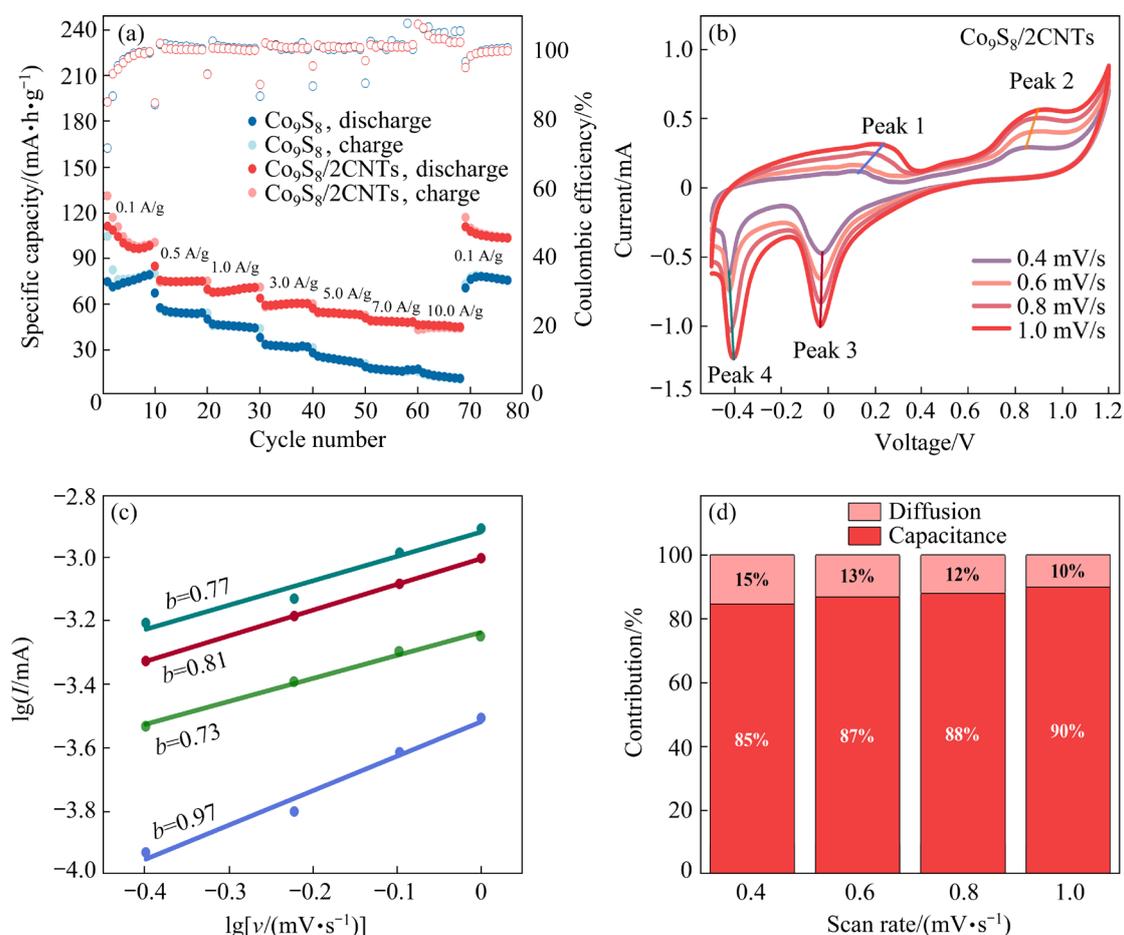

Fig. 5 Rate performances of Co_9S_8 and Co_9S_8/2CNTs at 0.1−10 A/g (a); CV curves at different scan rates (b) and corresponding lg I vs lg v plots of redox peaks (c) of Co_9S_8/2CNTs in Fig. 5(b); Diffusion/capacitance contributions at different scanning rates of Co_9S_8/2CNTs (d)

capacitors, capacitor contributions and diffusion-controlled Faraday intercalation processes. Generally, the measured peak current (I) in the CV curve and the corresponding scan rate (v) followed Eq. (1) [37]:

$$I=av^b \tag{1}$$

This can also be expressed as

$$\lg I=\lg a+b\lg v \tag{2}$$

where a and b are adjustable parameters. The b values of 0.5 and 1.0 were considered to be diffusion-controlled and capacitance-controlled processes, respectively. The calculated b values for the two pairs of redox peaks were 0.97, 0.73, 0.81 and 0.77 (Fig. 5(c)), indicating the combination of capacitance-controlled and diffusion-controlled behaviors.

In addition, diffusion/capacitance contribution at different scan rates could be calculated by Eq. (3):

$$I=k_1v+k_2v^{1/2} \tag{3}$$

where k_1v and $k_2v^{1/2}$ denote the capacitance and diffusion contributions, respectively. Therefore, the capacitive contributions could be calculated as 85%, 87%, 88% and 90% at scan rates of 0.4, 0.6, 0.8 and 1.0 mV/s (Fig. 5(d)), respectively, and only minor diffusion-controlled behaviors could be obtained.

3.4 Reaction mechanism

To reveal the structural evolution and chemical state changes of Co_9S_8 during NH_4^+ intercalation/deintercalation processes, XRD, FT-IR and XPS spectra at different states were recorded (Reference supporting information for equipment used for material characterization). During the first charge process ($a-b$ in Fig. 6(a)), a new diffraction peak corresponding to $CoSO_4\cdot6H_2O$ (PDF# 16-0304) appeared in the XRD spectra, indicating partly oxidized Co_9S_8. After the discharge to −1 V (Point e in Fig. 6(a)), the newly generated $CoSO_4\cdot6H_2O$ returned to Co_9S_8 (Figs. 6(a, b)). From the magnified diffraction peaks (Fig. 6(b)), the (311) diffraction peaks shifted to low angles upon discharging and recovered the original position upon charging, indicating Co_9S_8 lattice expansion and shrinkage [38]. The highly reversible structural evolution of the Co_9S_8/2CNTs microspheres during

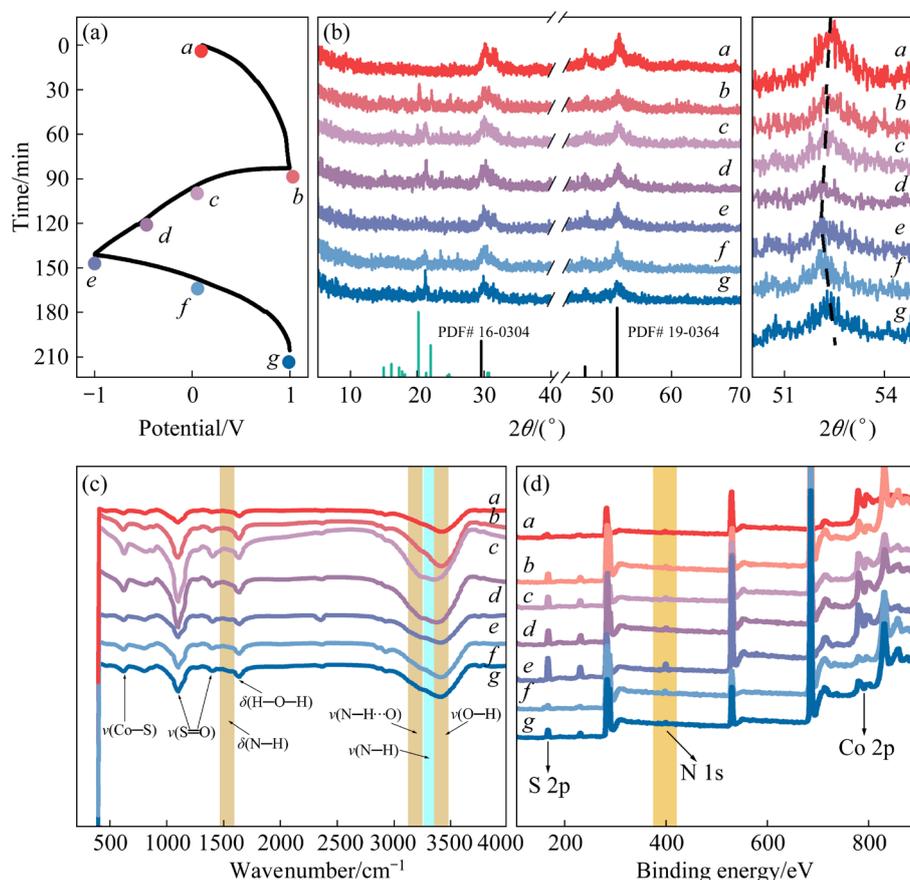

Fig. 6 Spectroscopic analysis of electrochemical reaction mechanism of Co_9S_8/2CNTs electrode: (a) Charge–discharge curve; (b) XRD patterns; (c) FT-IR characterization; (d) XPS spectra

the charge/discharge processes was the intrinsic manifestation of the excellent cycling stability.

The bonding chemistry between NH_4^+ and the host materials was investigated by FT-IR and XPS measurements (Figs. 6(c, d)). The peaks at 3422 and 1629 cm^{-1} were assigned to the stretching and bending vibrations of the O—H bond of chemisorbed water. The absorption peaks located at 1404 and 3145 cm^{-1} were credited with the bending and stretching vibrations of N—H [39,40]. The two peaks gradually increased upon discharging and recovered upon charging, indicating NH_4^+ intercalation/deintercalation. The peaks at 1093 and 1394 cm^{-1} were attributed to the symmetric and asymmetric vibrations of the S=O bond. The variation in the peaks demonstrated partial oxidation of Co_9S_8 in the charge processes and incomplete reduction of $CoSO_4 \cdot H_2O$ in the discharge processes. Meanwhile, the N—H···O hydrogen bond signal was observed near 3220 cm^{-1}, indicating the formation of hydrogen bonds between the inserted NH_4^+ and the oxidized Co_9S_8. After charging (e−g in Fig. 6(a)), the wide peak near 3220 cm^{-1} disappeared, indicating that the insertion/extraction of NH_4^+ ions in the Co_9S_8/2CNTs host was related to the oxidation/reduction of Co_9S_8 and building/breaking of hydrogen bonds [20,41,42]. This was also supported in the XPS survey spectra (Figs. 6(d) and 7(c)). The N 1s peak increased with NH_4^+ intercalation, and the XPS spectrum of N 1s moved to a higher binding direction, while the

charge process was reversed, further indicating the interaction between NH_4^+ and the matrix material (Figs. 6(d) and 7(b)).

The S 2p XPS spectrum of Fig. 7(a) was fitted to three peaks from S in Co_9S_8 (162 eV), C—S—C (163.5 eV), and SO_4^{2-} (167.6 eV). The presence of SO_4^{2-} in the original electrode plate (Point a in Fig. 6(a)) should be related to the partial oxidation of the sample. After the first charge (Point b in Fig. 6(a)), the binding energy of SO_4^{2-} increased significantly, indicating formation of $CoSO_4 \cdot 6H_2O$, which partially recovered upon discharging (Point e in Fig. 6(a)). From the N 1s spectra (Fig. 7(b)), peak states of —N—H—(NH_3) and —N+H—(NH_4^+) were obviously found, originating from two different states of NH_4^+ ions. Compared with the pristine state and the charged state, the ratio of —N—H—/—N+H— was significantly increased, demonstrating that more intercalated NH_4^+ ions existed in the form of NH_3. The N atom at 398.9 eV was ascribed to the C—N bond, which could originate from the interaction between the carbon nanotubes and the intercalated NH_4^+ ions [43,44].

The Co 2p spectrum (Fig. 7(c)) consisted of two spin-orbit doublets characterized by Co^{3+} (778.3, 794.1 eV) and Co^{2+} (780.2, 796.9 eV) and two shaking satellites [30,31]. Compared with State b (1.26:1), the ratio of Co^{3+}/Co^{2+} calculated by the corresponding integral peak area in the complete discharge state was 0.44:1. Owing to the embedding

**Fig. 7** High-resolution spectra of S 2p (a), N 1s (b) and Co 2p (c) corresponding to Co_9S_8/2CNTs circulating at different potentials during charge−discharge processes (a−g corresponding to Points a−g in Fig. 6(a))

of NH_4^+, the content of Co^{3+} decreased, while the content of Co^{2+} increased significantly. When charged to 0.3 V (Point f), the ratio of Co^{3+}/Co^{2+} increased to 1.17:1 due to NH_4^+ extraction. After being fully charged, the Co^{3+}/Co^{2+} ratio recovered to 1.23:1. The reversible charge transfer reaction showed that $Co_9S_8/2CNTs$ was suitable electrode material for NH_4^+ accommodation; in terms of reaction chemistry, this could be attributed to the unusual hydrogen bonding interaction between NH_4^+ and the material, which contributed to the ultrafast storage kinetics of NH_4^+ [21,23,45,46].

3.5 Kinetic analysis

The aqueous ammonium-ion batteries assembled with $Co_9S_8/2CNTs$ microspheres as the cathode and active carbon as the anode were evaluated under a practical operating voltage of 0.01−1.00 V. The CV curves presented a pair of distinct redox peaks (Fig. S2 in SI), indicating that NH_4^+ ions could be reversibly inserted/extracted from $Co_9S_8/2CNTs$ microspheres. From the second scan, the CV curves could exactly overlap, suggesting the good cycling ability of $Co_9S_8/2CNTs$ microspheres. The galvanostatic charge–discharge curves of the $Co_9S_8/2CNTs$ microspheres (Fig. S3 in SI) exhibited a pair of voltage plateaus in the initial charge and discharge cycle, indicating that NH_4^+ was reversibly inserted/extracted from the $Co_9S_8/2CNTs$ microspheres, which was consistent with the CV results. For the next 10−60 cycles, the voltage platform remained in the same position. The $Co_9S_8/2CNTs$ microspheres (Fig. 8) provided 60, 46, 39, 32, 28, 27 and 25 mA·h/g at current densities of 0.1, 0.5, 1.0, 3.0, 5.0, 7.0 and 10.0 A/g, respectively, suggesting a good rate performance. Impressively, when the current density was continuously decreased to 0.1 A/g, it still provided a discharge specific capacity of 57 mA·h/g with a ratio of 95%. Table S1 in SI demonstrates the performance of various NH_4^+ cathode host materials, and it can be inferred that the specific capacity of Co_9S_8 as an ammonium ion battery cathode material is superior to some of the reported ammonium ion battery materials, such as NiHCF (38 mA·h/g at 0.5 A/g) and NiAPW (51.3 mA·h/g at 0.3 A/g), and is only followed by some vanadium- and manganese-based composite cathode materials.

The evolution of charge transfer during cycling was investigated by electrochemical impedance

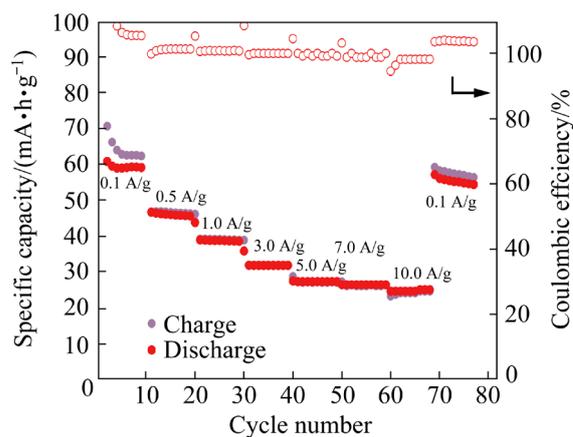

Fig. 8 Electrochemical performance of $Co_9S_8/2CNTs$ cathode in voltage window of 0.01−1.00 V and rate performance of $Co_9S_8/2CNTs$ cathode at 0.1−10.0 A/g

spectroscopy (EIS) and galvanostatic intermittent titration technique (GITT). All Nyquist plots consisted of a semicircle in the high-frequency region and a linear part in the low-frequency region, where the semicircle region represented the charge transfer impedance (R_{ct}), and the intercept of the real axis in the high-frequency range corresponded to the ohmic resistance (R_s). In the EIS plot measured before cycling (Fig. 9(a)), the R_{ct} of the $Co_9S_8/2CNTs$ microspheres was smaller than that of the Co_9S_8 microspheres. Figures 9(b, c) illustrate the change in R_{ct} and R_s (related to byproducts) as a potential function. Upon charging, an increased R_s was observed due to the formation of $CoSO_4·6H_2O$ with poor conductivity [47]. The R_s values could recover upon discharging due to the reversible reduction of $CoSO_4·6H_2O$. Meanwhile, R_{ct} showed a gradually decreasing trend in the discharge process, and the impedance increased after decreasing to platform $b-c$ in Fig. 6(a), which was caused by the volume expansion of the $Co_9S_8/2CNTs$ microspheres. In the subsequent charging to plateaus $e-f$ in Fig. 6(a), R_{ct} and R_s reached the bottom. The charge transfer resistance of the $Co_9S_8/2CNTs$ microspheres was 4.6 Ω before the charge and discharge processes and 2.5 and 0.3 Ω after the discharge and charge processes, indicating that the reduction in charge transfer resistance was related to activation processes [48,49].

The diffusion coefficient of ammonium ions can be derived using Eq. (4) (please refer to the supporting information for details) [50]:
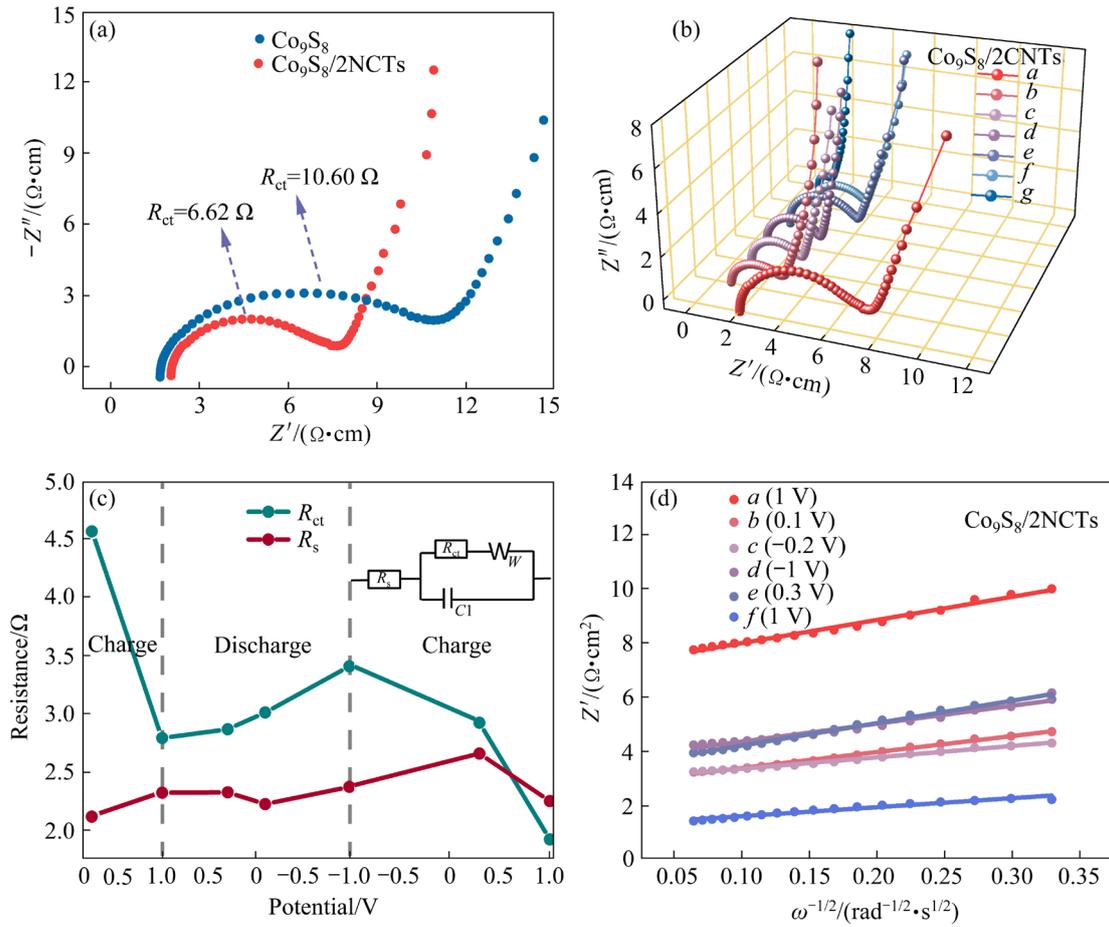

Fig. 9 (a) Precycle Nyquist plots of Co$_9$S$_8$ and Co$_9$S$_8$/2CNTs cathodes; (b) Nyquist plots obtained at various potentials during the 1st cycle of Co$_9$S$_8$/2CNTs cathode; (c) R_s and R_{ct} at different potentials (inset shows the equivalent circuit for fitting the EIS curve) of Co$_9$S$_8$/2CNTs cathode; (d) Corresponding linear curves of Z' vs $\omega^{-1/2}$ in low-frequency region of Co$_9$S$_8$/2CNTs cathode

$$D=\frac{R^2 T^2}{2 A^2 n^4 F^4 C^2 \sigma^2} \quad (4)$$

The ammonium-ion diffusion coefficients (denoted by $D(NH_4^+)$) in the Co$_9$S$_8$ and Co$_9$S$_8$/2CNTs microspheres were calculated to be as high as 2.58×10^{-10} and 8.25×10^{-10} cm^2/s, respectively. This result demonstrated that the ammonium-ion reaction kinetics of Co$_9$S$_8$/2CNTs microspheres was remarkably fast. In addition, the relationships between Z' and the inverse square root of the angular frequency ($\omega^{-1/2}$) are shown in Fig. 9(d). According to the slope of the fitted $Z'-\omega^{-1/2}$ curve, the Warburg coefficients during the first cycle were 8.5, 6.2, 5.9, 4.2, 6.6, 8.3 and 3.3. The ion diffusion coefficients were inversely proportional to the slope of the fitted curve of $Z'-\omega^{-1/2}$, which was consistent with the available literature. During the first cycle from the Co$_9$S$_8$/2CNTs microspheres discharged to

platform $c-d$ in Fig. 6(a), $D(NH_4^+)$ increased, and when discharged to -1 V (Point e in Fig. 6(a)), $D(NH_4^+)$ decreased to 1.37×10^{-8} cm^2/s, and when charged to 1 V (Point g in Fig. 6(a)), $D(NH_4^+)$ increased to the maximum value of 5.47×10^{-8} cm^2/s. These results demonstrated the improved capacity and rate performance.

The ammonium-ion diffusion coefficients were also measured by the GITT technique (Fig. 10). It was calculated based on the following Eq. (5) (refer to supporting information for details) [51]:

$$D=\frac{4}{\pi \tau}\left(\frac{m_B V_m}{M_B S}\right)^2 \left(\frac{\Delta E_s}{\Delta E_\tau}\right)^2 \quad (5)$$

The NH$_4^+$ diffusion coefficients in the Co$_9$S$_8$/2CNTs microspheres were calculated to be approximately $10^{-7}-10^{-9}$ cm^{-2}/s, and the results were in good agreement with the EIS results. A

relatively stable trend of $D(\mathrm{NH_4^+})$ could be observed throughout the charge-discharge testing processes, indicating the rapid and stable diffusion behavior of $\mathrm{NH_4^+}$ ions during insertion/extraction from the $\mathrm{Co_9S_8}$ host.

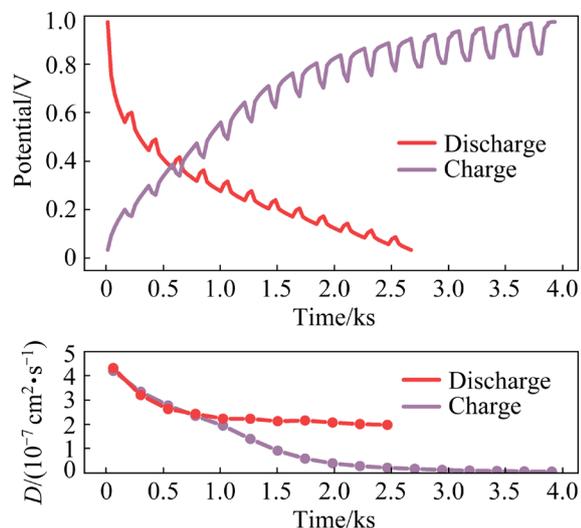

Fig. 10 Charge–discharge curves of $\mathrm{Co_9S_8}/2\mathrm{CNTs}$ cathode and corresponding $\mathrm{NH_4^+}$ diffusion coefficient (D)

4 Conclusions

(1) CNTs introduction could improve the dispersion of the material, widen the lattice spacing and increase the specific surface area of material; moreover, it could improve the electron transfer and restrain the volume variation and dissolution of polysulfides during the cycling processes.

(2) The $\mathrm{Co_9S_8}/2\mathrm{CNTs}$ microspheres were revealed to be favorable to the rapid penetration of electrolyte and the short diffusion distance of ammonium ions.

(3) The reversible phase transition between $\mathrm{Co_9S_8}$ and $\mathrm{CoSO_4 \cdot 6H_2O}$ was found during the charge/discharge process. Moreover, the highly reversible insertion/extraction of $\mathrm{NH_4^+}$ ions in the $\mathrm{Co_9S_8}$ host was accompanied by the building/breaking of intermolecular hydrogen bonds.

(4) The $\mathrm{Co_9S_8}/2\mathrm{CNTs}$ microspheres were considered potential cathodes for the aqueous ammonium-ion batteries.

摘　要：构建 Co_9S_8/碳纳米管(Co_9S_8/2CNTs)涂层微球，并成功将其应用于水性铵离子电池。在 Co_9S_8 微球中引入碳纳米管可增加电子传导性，缩短 NH_4^+ 离子的扩散距离，并提高对循环过程中体积变化的缓冲能力。因此，Co_9S_8/2CNTs 微球在 0.1 A/g 条件下具有 112 mA·h/g 的可逆容量。此外，研究了 Co_9S_8/2CNTs 中伴随着可逆相变产物 $CoSO_4·6H_2O$ 的形成和分子间氢键的形成/断裂的铵离子储能机理。
