Abstract: To reduce the friction coefficient of the superhard TiAlSiN composite coating, TiAlSiN/WS2 multilayers were synthesized by multiple plasma immersion ion implantation and deposition as well as radio-frequency (RF) magnetron sputtering. X-ray diffraction (XRD), scanning electron microscopy (SEM), Raman spectrum, nano indentation, tribological and electrochemical tests were employed to characterize the microstructure, mechanical properties and corrosion behavior of the as-deposited multilayers. SEM results reveal that the TiAlSiN/WS2 multilayers have a good periodicity. Nano indentation results show that the nanohardness of TiAlSiN/WS2 multilayers is between that of the TiAlSiN and WS2 coatings. Tribological tests prove that the friction coefficient of the TiAlSiN/WS2 multilayers is lower and more stable than that of the TiAlSiN coating. In addition, the TiAlSiN/WS2 multilayers show excellent corrosion resistance and the corrosion current density decreases obviously at a relative small modulation period.

Key words: TiAlSiN; WS2; multilayer; friction coefficient; corrosion resistance

1 Introduction

In recent years, nanocomposite coatings (TiAlN, TiSiN and TiAlSiN) with hardness higher than 40 GPa have attracted extensive attentions because of their unique mechanical, chemical and wear properties [1−5]. Unfortunately, these coatings usually lack lubricating properties and exhibit a relatively high friction coefficients (0.6−1.0) at room or elevated temperatures [6−8]. Since a low friction coefficient can effectively reduce the contact temperature during the high speed and dry cutting process, nanocomposite coatings with super hardness and self-lubrication properties have great potential for improving the lifetime and the performance of cutting tools. Some researchers have mixed carbon into the composite coating and obtained a low friction coefficient [9−12].

Tungsten disulphide (WS2) has been used widely in space applications due to its extremely low friction coefficient and long lifetime [13−14]. However, since the structure of tungsten disulfide (WS2) is similar to that of molybdenum disulfide (MoS2), its wear resistance deteriorates significantly when it is working in humid atmosphere [15−16]. Pervious study proposed that the MoS2/Ti multilayer structure was beneficial for increasing the resistance of the MoS2 film to the moisture attack [17]. In order to reduce the friction coefficient of the TiAlSiN coating as well as increase the resistance to moisture atmosphere, TiAlSiN/WS2 multilayer coatings were fabricated and their mechanical performance and corrosion behaviors were studied.

2 Experimental

Si (100) wafer and polished M2 (W18Cr4V) tool steel were used as substrates. Fabrication of the TiAlSiN/WS2 coating was carried out in a multi-purpose plasma immersion ion implantation and deposition facility [18]. The TiAlSiN layer was fabricated by the multi-cathode plasma source using pure Ti (99.9%) and SiAl alloy (70%:30%, mass ration) cathodes. The WS2 layer was obtained by the radio-frequency (RF) magnetron sputtering system. By controlling the working time of the multiple-cathode arc plasma source and the sputtering target, TiAlSiN/WS2 multilayer coatings with various modulation periods were obtained. The parameters for synthesizing the TiAlSiN layer are displayed as follows: a pressure (N2) of 0.3 Pa, a pulse bias voltage of 20 kV, a pulse repetition frequency of 50
Hz, a pulse bias voltage duration time of 60 µs, a pulse duration time for the Ti cathode of 2 ms, a pulse duration time for the SiAl cathode of 2 ms. The WS2 layer was deposited using the following parameters: a RF power of 600 W, a pressure (Ar) of 2 Pa, a bias voltage of 6 kV, a pulse repetition frequency of 100 Hz, a bias voltage duration time of 60 µs. The further processing parameters for different multilayers are shown in Table 1.

The crystalline structure of the films was determined by X-ray diffraction (XRD, Philips-X’pert) with Cu Kα radiation, and the diffraction angle was scanned from 20° to 90°. A high-resolution field emission scanning electron microscopy (SEM, FEI-Quanta–200) was used to study the cross sectional microstructure of the coatings. A MTS XP nano-indentation system was used to measure the nanohardness of the coatings in a mode of continuous stiffness measurement, and six indentations were conducted in each sample. The tribological properties were characterized by a ball-on-disc test with a load of 2 N on the sample through a 6.3 mm Si3N4 ball, and a line speed of 7.5 m/min was used during the test. The wear tracks of the coatings were observed by an optical microscope (OLYMPUS-PMG3). In addition, Raman spectroscopy was used to characterize the structure of wear tracks. Corrosion properties of all films were evaluated by the anode polarization curve tests in a saturated 3.5% NaCl solution with high purity graphite as the counter cathode, and a saturated calomel electrode (SCE) as reference electrode.

3 Results and discussion

3.1 Composition and microstructure

Figure 1 displays the XRD patterns of all samples. According to XRD results, the preferred orientation in the TiAlSiN coating is TiN(200). The coating in sample W1 also exhibits a TiN structure and no obvious WS2 peak can be found. However, the coating in sample W2 exhibits a strong WS2 peak and the intensity of TiN peak decreases greatly. This structural transformation of TiAlSiN/WS2 multilayer may be attributed to the damage effect by a high energy ion implantation [17–18]. For sample W1, because the WS2 layer is very thin (<60 nm), high energy ion bombardment in the deposition process will change WS2 to be an amorphous phase. However, since the coating in sample W2 has a thick WS2 layer (>400 nm), high energy ion bombardment has negligible influence on the structure of WS2. Consequently, a large intensity of WS2 peaks can be found in sample W2.

Figure 2 presents the cross-sections of samples T0 and W1 on Si wafer. According to Fig. 2(a), the TiAlSiN
coating shows a typical columnar structure. However, the cross section of the TiAlSiN/WS₂ multilayer shown in Fig. 2(b) exhibits an obvious layered structure formed in the coating. In addition, because a high energy ion implantation was applied during the layer deposition, the interface between adjacent layers was not very clear.

3.2 Mechanical properties

Figure 3 shows the nanohardness of all samples. The TiAlSiN coating (sample T0) has a high hardness of 35 GPa. The WS₂ coating has a low hardness of 5 GPa. The hardness of the TiAlSiN/WS₂ multilayer with the modulation period of 100 nm is about 16 GPa, and it decreases to 11 GPa as the modulation period increases to 600 nm.

**Fig. 3** Hardness of all samples

Figure 4 shows the friction coefficient curves of all samples. The WS₂ coating exhibits excellent wear performance and its friction coefficient is about 0.11. The TiAlSiN coating shows a high friction coefficient of about 0.82. The TiAlSiN/WS₂ multilayer coating exhibits an improved wear performance, and the friction coefficients of samples W1 and W2 are about 0.53 and 0.34, respectively, which is lower than that of the TiAlSiN coating.

![Graph showing friction coefficient curves](image)

**Fig. 4** Friction coefficient curves of all samples

Figure 5 shows the wear tracks of samples T0 and W1 as well as corresponding Si₃N₄ balls. According to Figs. 5(a) and 5(b), the width of the wear track in sample T0 is about 640 μm and the diameter of the wear track on the corresponding Si₃N₄ ball is about 650 μm. Figures 5(c) and 5(d) reveal that the width of the wear track is about 420 μm and the diameter of the wear track on the corresponding Si₃N₄ ball is about 450 μm. Comparing the friction curves and wear tracks of sample T0 with W1, it is clear that the TiAlSiN/WS₂ multilayer exhibits excellent wear performance and self-lubricating properties.

![Graph showing wear tracks](image)

**Fig. 5** Wear tracks of samples T0 and W1

Figure 6 shows the Raman analysis for the wear track of sample W2. Peaks at 340, 410 and 550 cm⁻¹ prove the presence of WS₂ inside the wear track. However, WO₃ peaks at 650 and 801 cm⁻¹ also present inside the wear track, which should be deduced from the oxygen pollution during the deposition process. Based on the tribological and Raman results, the self-lubricating properties of the multilayers should be originated from the introduction of the WS₂.

**Fig. 6** Raman analysis for the wear track of sample W2

Figure 7 shows the anode polarization curves of all samples. The corrosion current densities and corrosion potentials derived from these curves are listed in Table 2. It can be found that the corrosion current densities of samples W1 and W2 are lower than that of samples T0 and S0. Sample W1 with the modulation period of 100 nm possesses the lowest corrosion current density.

Table 2 Corrosion potentials and corrosion current densities

Figure 8 exhibits the surface morphologies of samples T0, S0 and W1 after the anode polarization curve tests. It is obvious that a larger amount of big and deep corrosion pits are formed on the surfaces of samples T0 and S0. However, the surface of the sample W1 is smooth and few corrosion pits can be found. In accordance with the anode polarization curves and optical images, it can be found that the TiAlSiN/WS₂ multilayer coatings possess excellent corrosion resistance.

![Surface morphologies](image)

**Fig. 8** Surface morphologies of samples T0, S0 and W1
In general, the TiAlSiN coating possesses a columnar structure, which usually contains a lot of growth defects, such as holes and interstices. In addition, the WS$_2$ coating synthesized by magnetron sputtering has similar structure. Apparently, these growth defects and low surface density will provide corrosive channels and eventually lead to the reduction of corrosive nature. However, the TiAlSiN/WS$_2$ multilayer coatings contain a lot of interfaces, which can effectively prevent the formation of columnar structure and large growth defects. Therefore, the TiAlSiN/WS$_2$ multilayer coatings possess excellent anti-corrosion properties.

4 Conclusions

1) The TiAlSiN/WS<sub>2</sub> multilayer coatings fabricated by multi plasma immersion ion implantation as well as the magnetron sputtering possess a typical layered structure.

2) The nanohardness and friction coefficient of TiAlSiN/WS<sub>2</sub> multilayer coatings are both between those of the TiAlSiN and WS<sub>2</sub> coatings.

3) The TiAlSiN/WS<sub>2</sub> multilayer coatings present excellent corrosion resistances and the corrosion current density decreases with the modulation period.

摘 要: 为了降低超硬 TiAlSiN 复合涂层的摩擦因数, 采用多元等离子体浸没离子注入与沉积和射频(RF)磁控溅射技术制备 TiAlSiN/WS₂多层薄膜, 利用 XRD、SEM、Raman 光谱、纳米探针、摩擦和电化学试验对薄膜的微结构、力学性能和腐蚀行为进行测试与分析。SEM 结果表明: TiAlSiN/WS₂多层薄膜具有清晰的调制周期。纳米硬度结果表明, TiAlSiN/WS₂多层薄膜硬度介于 TiAlSiN 和 WS₂涂层硬度之间。摩擦实验结果证实 TiAlSiN/WS₂多层薄膜的摩擦因数低于 TiAlSiN 涂层的, 且摩擦过程平稳。此外, TiAlSiN/WS₂多层薄膜表现出良好的抗腐蚀能力, 在相对较短的调制周期内, 其腐蚀电流密度显著降低。
